# Calculus with Parametric Curves

### Key formulas

**Parametric equations** are equations that define x and y as functions of a third variable t (called the **parameter**):

$$x = f(t), y = g(t).$$

Plugging a specific value of t into the equations for x and y determine a point (x, y) = (f(t), g(t)) in the xy-plane. As t varies, the point (x, y) = (f(t), g(t)) varies and traces out a curve C, called a **parametric curve**. We can **eliminate the parameter** to find a rectangular equation that represents the graph of a set of parametric equations.

**Differentiation:** Given a set of parametric equations x = f(t), y = g(t), we have

$$\frac{dy}{dx} = \frac{dy/dt}{dx/dt} = \frac{g'(t)}{f'(t)}, \text{ provided } \frac{dx}{dt} \neq 0$$
$$\frac{d^2y}{dx^2} = \frac{d}{dx} \left[\frac{dy}{dx}\right] = \frac{\frac{d}{dt} \left[\frac{dy}{dx}\right]}{\frac{dx}{dt}}.$$

The first derivative helps us find slopes of tangent lines to a parametric curve. The second derivative helps us determine concavity of the curve.

Arc Length: If a smooth parametric curve  $C : x = x(t), y = y(t), a \le t \le b$  does not intersect itself on the interval  $a \le t \le b$  (except possibly at the endpoints), the the arc length of C on the interval is given by

$$L = \int_a^b \sqrt{\left(\frac{dx}{dt}\right)^2 + \left(\frac{dy}{dt}\right)^2} dt = \int_a^b \sqrt{(f'(t))^2 + (g'(t))^2} dt$$

The area S of the surface of revolution formed by rotating C about the x-axis (assuming  $g(t) \ge 0$ ) is

$$S = 2\pi \int_{a}^{b} g(t) \sqrt{\left(\frac{dx}{dt}\right)^{2} + \left(\frac{dy}{dt}\right)^{2}} dt,$$

and about the y-axis (assuming  $f(t) \ge 0$ ) is

$$S = 2\pi \int_{a}^{b} f(t) \sqrt{\left(\frac{dx}{dt}\right)^{2} + \left(\frac{dy}{dt}\right)^{2}} dt.$$

# Example 1: Sketch a curve described by parametric equations. Indicate the direction in which the curve is traced as the parameter increases and find the rectangular equation by eliminating the parameter. $x = \sqrt{t}, y = t - 5$ , where $t \ge 0$ .

Example 2: Using trigonon	metry to eliminate the parameter	
Eliminate the parameter to fin	nd the rectangular equation for the curve. Identify the curve.	
1. $x = \cos(t), y = \sin(t)$ whe	here $0 \le t \le 2\pi$ . 2. $x = -3 + 4\cos(t), y = 2 + 5\sin(t)$ where $0 \le t \le 2\pi$	π.

Example 3: Finding a derivative	
Find $\frac{dy}{dy}$ for the curve given by	
1. $x = \sqrt[3]{t}, y = 4 - t$	2. $x = 2e^{\theta}, y = e^{-\theta/2}$
